Graphical Abstract

The 2D Nb$_2$O$_5$@RuO$_2$ heterostructures possess short diffusion length of ions/electrons, easy penetration of liquid electrolyte, and high conductivity transport of electrons.
Constructing two-dimensional (2D) heterostructured materials by stacking different 2D materials could combine the merits of the individual building blocks while getting rid of the associated shortcomings. Orthorhombic Nb$_2$O$_5$ (T-Nb$_2$O$_5$) is one of the greatly promising candidates for durable and safety anode for Li-ion batteries (LIBs), but it usually exhibits poor electrochemical performance due to the low electronic conductivity. Herein, we realize excellent lithium storage performance of T-Nb$_2$O$_5$ by designing 2D Nb$_2$O$_5$@2D metallic RuO$_2$ heterostructures (Nb$_2$O$_5$@RuO$_2$). The presence of 2D metallic RuO$_2$ leads to enhanced electronic conductivity. The 2D Nb$_2$O$_5$@RuO$_2$ heterostructures possess very short diffusion length of ions/electrons, easy penetration of liquid electrolyte, and high conductivity transport of electrons through the 2D metallic RuO$_2$ to 2D Nb$_2$O$_5$. The Nb$_2$O$_5$@RuO$_2$ delivers remarkable rate performance (133 mAh g$^{-1}$ and 106 mAh g$^{-1}$ at 50 C and 100 C) and excellent long-life capacity (97 mAh g$^{-1}$ after 10000 cycles at 50 C). Moreover, Nb$_2$O$_5$@RuO$_2$/LiFePO$_4$ full batteries also display high rate capability of 140 mAh g$^{-1}$ and 90 mAh g$^{-1}$ at 20 C and 50 C, respectively. Theoretical calculation results show that the 2D Nb$_2$O$_5$@RuO$_2$ heterostructures possess more large adsorption ability for Li$^+$ than that of Nb$_2$O$_5$, indicating an excellent lithium storage performance.

1. Introduction

Nowadays, the energy crises and environmental pollution resulting from the overdependence of fossil fuels have drawn the worldwide attention. There is an increased demand for developing clean and renewable energy. Lithium-ion batteries (LIBs), as chemically storing energy devices, have been widely applied in portable electronic devices and demonstrated as promising energy storage system for hybrid electric vehicles (HEVs), electric vehicles (EVs), and smart grids.[1-3] The developments of LIBs with high energy density and high power density rely heavily on the high performance electrode materials. Graphite is the most conventional anode material for LIBs, which possesses a lithiation potential of below 0.2 V (vs. Li$^+/Li$).[4] Such low lithiation potential induce major safety issues due to the electrolytic
decomposition and lithium dendrites formation. Furthermore, it displays unsatisfactory capacity at high current density due to its low Li ion diffusion coefficient and the formation of solid electrolyte interphase (SEI) on its surfaces.\[^{5-8}\] Typical insertion-type anode materials, such as Li\(_3\)Ti\(_5\)O\(_{12}\),\[^{9-10}\] TiNb\(_2\)O\(_7\),\[^{11-12}\] orthorhombic Nb\(_2\)O\(_5\),\[^{13-15}\] are investigated extensively because of their better capacity retention than conventional and alloy-type ones. Among them, orthorhombic Nb\(_2\)O\(_5\) (T-Nb\(_2\)O\(_5\)) has shown excellent lithium ions pseudocapacitive in nonaqueous electrolytes since the empty octahedral sites between (001) planes offer natural tunnels for lithium ion transport.\[^{16}\] When used for LIBs, the T-Nb\(_2\)O\(_5\) shows a suitable voltage range from 1.1 to 2.0 V vs. Li\(^+\)/Li, corresponding to a comparatively high reversible theoretical capacity of about 200 mAh g\(^{-1}\) to form Li\(_x\)Nb\(_2\)O\(_5\) (x = 2).\[^{13, 17-20}\] Moreover, it can use aluminum foil as the anode current collector rather than expensive and heavy copper foil, because Li does not alloy with aluminum above 0.3 V vs. Li\(^+\)/Li.\[^{21-22}\] However, the intrinsic drawback of poor electrical conductivity (\(\approx 3 \times 10^{-6} \) S cm\(^{-1}\)) and severe pulverization during charge/discharge prevent its practical applications for high performance LIBs.\[^{23}\]

Considerable attention has been made to enhance the electrochemical performance of T-Nb\(_2\)O\(_5\). Construction of nanosized T-Nb\(_2\)O\(_5\) (i.e. nanobelts,\[^{24}\] vein-like nanoporous networks,\[^{25}\] hierarchical microspheres\[^{26}\] and nanofibers\[^{27}\]) is one of the most effective approaches. Another strategy for overcoming low electronic conductivity is to mix Nb\(_2\)O\(_5\) with conductive materials such as graphene,\[^{28}\] carbon nanotubes (CNTs),\[^{29-30}\] graphite\[^{31}\] and many others. When used for energy storage system, two-dimensional (2D) materials show unprecedented properties that differ from their bulk systems, because the characteristic time constant \(\tau\) for ion diffusion is proportional to the square of the diffusion length \(L\) (\(\tau \approx L^2/D\)).\[^{32}\] Single-crystalline mesoporous T-Nb\(_2\)O\(_5\) nanosheets/graphene composites have demonstrated enhanced intercalation/deintercalation characteristics by shortening ions diffusion length and accelerating electron transport.\[^{33}\] 2D heterostructured materials, prepared by stacking different 2D crystals on top of each other at the nanoscale, could combine the collective advantages of individual building blocks and synergistic properties. In addition, the 2D heterostructured materials have high specific surface area, enabling improved performances for surface dominant reactions. Gogotsi \textit{et al} reported that MoS\(_2\)-on-MXene heterostructures show high performance lithium storage performance.\[^{34}\] One can expected that rational design 2D T-Nb\(_2\)O\(_5\)@2D metallic metal oxide heterostructures could significantly improve its energy storage properties. Among 2D metal oxides, RuO\(_2\) nanosheets are considered to be the most promising materials.
promising metal oxides because of their metal-like electrical conductivity, which exhibits a highly conductive property ($\approx 2 \times 10^4$ S cm$^{-1}$)$^{[20,35]}$ and fast Li permeation.$^{[36]}$

In this work, we designed 2D Nb$_2$O$_5$@2D metallic RuO$_2$ heterostructures (denoted as Nb$_2$O$_5$@RuO$_2$) as anode for high performance LIBs. This unique 2D heterostructures combine a variety of advantages: 1) The intimate interfacial interaction between T-Nb$_2$O$_5$ and the metallic RuO$_2$ can not only facilitate the electron transfer, but also offer high electrode/electrolyte contact surface area for quick electrolyte infiltration, reaching the full potential of the active material (Nb$_2$O$_5$). 2) The confined thickness within a nanoscale range of Nb$_2$O$_5$@RuO$_2$ shorten the diffusion length of lithium ions. 3) The Nb$_2$O$_5$ nanosheets possess strong interaction with RuO$_2$ nanosheets, which keeps the structure stability of Nb$_2$O$_5$@RuO$_2$ after repeated Li$^+$ intercalation/deintercalation, thus leading to excellent electrochemical performance. When used as anode for LIBs, the Nb$_2$O$_5$@RuO$_2$ can deliver excellent cyclability and rate performance, which demonstrates capacity of 100 mAh g$^{-1}$ after 10000 cycles at 50 C. Additionally, a full battery has been assembled by using Nb$_2$O$_5$@RuO$_2$ and LiFePO$_4$ as anode and cathode, respectively. The full battery demonstrates enhanced charge and discharge ability (140 mAh g$^{-1}$ and 90 mAh g$^{-1}$ at 20 C and 50 C, respectively). Moreover, theoretical calculations reveal the presence of the RuO$_2$ layer indeed improves the stability of lithium ions adsorption and reduces the diffusion barrier of lithium ions in the Nb$_2$O$_5$.

2. Materials and methods

2.1. Materials synthesis

As reported previously,$^{[35,37]}$ The KNb$_3$O$_8$ and NaRuO$_2$ were synthesized by calcination of stoichiometric Nb$_2$O$_5$ and K$_2$CO$_3$ at 900 °C for 10 h in air and Na$_2$CO$_3$, Ru and RuO$_2$ at 900 °C for 12h in Ar atmosphere, respectively. Protonation was realized by mixed KNb$_3$O$_8$ and NaRuO$_2$ with acid aqueous for one week. In a typical procedure, 1.0 g of KNb$_3$O$_8$ and NaRuO$_2$ were dispersed in 60 mL nitric acid (6 mol L$^{-1}$) and 500 mL hydrochloric acid (1 mol L$^{-1}$), respectively. The exfoliation of HNb$_3$O$_8$ and HRuO$_2$ were achieved by intercalation of tetrabutylammonium (TBA) cation into the layer. Note that the TBA$^+$/H$^+$ = 5. The resultant solution was shaken for two weeks and followed by ultrasonic treatment. Subsequently, the suspensions were centrifuged at 2000 rpm for 30 min to separate the non-exfoliated sediment. The dry TBA-Nb$_3$O$_8$ and TBA-RuO$_2$ were obtained by after centrifugal separation and drying in vacuum freeze.
drier. The TBA-Nb$_2$O$_8$ and TBA-RuO$_2$ were dissolved in water with mass ratio of 6:1 to form uniform solution by stirring and ultrasonic dispersion. Subsequently, the Nb$_2$O$_3$@RuO$_2$ was obtained by freeze drying. Finally, the precursor was annealing at 600 °C for 2h in air. The pure Nb$_2$O$_3$ nanosheets were obtained by directly heating the TBA-Nb$_2$O$_8$ at same condition.

2.2. Materials characterization

The morphologies of samples were observed by scanning electron microscopy (CIQTEK SEM3100 and Hitachi, SU8200) and transmission electron microscopy (JEOL, JEM-2100F). The crystalline structure of samples was examined by X-ray diffraction (TTR-III, Rigaku). Bonding states of the atoms were investigated by XPS (Thermo-VG Scientific, ESCALAB 250). Raman spectrum was obtained by a LanRanHR (HORIBA Scientific, Paris, France) spectrometer. Nitrogen adsorption/desorption isotherms were characterized by an ASAP 2020 accelerated surface area and porosimetry system. The thermogravimetric analysis using TGA Q5000 instrument (10 °C/min from 30 to 800 °C in air).

2.3. Electrochemical characterization

To prepare the electrodes for 2032 coin cell assembly. The samples were mixed with acetylene black and poly(vinylidene) in a mass ratio of 7:2:1 in an N-methylpyrrolidone solvent. Then the slurry was coated on the copper foil and dried in vacuum oven 60 °C overnight. The cell was assembled in glove box (the water and oxygen concentrations were kept below 0.1 ppm), using Li metal as counter and reference electrode and Celgard 2400 as the separator. The electrolyte was composed of 1 M LiPF$_6$ dissolved in ethylene carbonate (EC) and dimethyl carbonate (DEC) (1:1, w/w). The CV curves and EIS were obtained on electrochemical workstation (CHI 660D). The charge and discharge were evaluated by battery test system (Neware BTS-610). For the fabrication of Nb$_2$O$_3$@RuO$_2$//LiFePO$_4$ full cell, the commercial LiFePO$_4$ electrode was used as cathode and the activated Nb$_2$O$_3$@RuO$_2$ was used as anode. The Nb$_2$O$_3$@RuO$_2$ electrodes used in the full cells were cycled in half cells before they were assembled into full cells. The full cell was fabricated with Nb$_2$O$_3$@RuO$_2$ as the anode and LiFePO$_4$ as the cathode with a mass ratio of 1:3, the capacity ratio of the negative electrode to positive electrode (N/P ratio) is about 0.67.

2.4. Theoretical Calculations
The calculations for structure optimization, self-consistent and energy barrier are carried out with the ABACUS package.\footnote{[38]} The exchange-correlation function is treated by the generalized gradient approximation (GGA) in the form of the Perdew-Burke-Ernzerhof (PBE) functional.\footnote{[39]} We use the SG15 optimized Norm-Conserving Vanderbilt (ONCV) multi-projector pseudopotentials to describe the electronic potential field of the core.\footnote{[40]} At the same time, the numerical atomic orbital basis set is expanded using Standard DZP Orbitals. The convergence criterion for electronic self-consistent calculations is 5.0E-7 eV. Both the atomic positions and the lattice parameters are allowed to change during the structural relaxation until the Hellmann-Feynman forces on each atom are lower than 2.0E-2 eV/Å. We employ numerically tabulated atom-centered orbitals as the basis functions to expand electronic wave functions. Specifically, we choose the basis sets 4s2p2d1f for Ru and Nb elements, 2s2p1d for O element and 4s1p for Li element. Brillouin-Zone (BZ) integration was sampled by Gamma point in the reciprocal space in order to improve computational efficiency. We take the van der Waals DFT-D3 interaction into account in the calculation of the Nb$_2$O$_5$@RuO$_2$ heterojunction system, which makes the simulation results more accurate.\footnote{[41]}

The establishment of hypothesis model of T-Nb$_2$O$_5$: Previous experimental fitting proposed a virtual crystal model of T-Nb$_2$O$_5$ (Nb$_{16.8}$O$_{42}$), but the fraction occupation of Nb or O made DFT calculation expensive. Therefore, we made the following rational approximations to the T-Nb$_2$O$_5$ structure model: (1) A small amount of the amorphous Nb cannot be considered because the location is not defined and stoichiometry is fractioned; (2) Two nearest Nb atoms (the distance is 0.43 Å, occupations are 0.5) are replaced with their average sites (occupations are 1.0) owing to avoid Nb deviating from the equilibrium positions during self-consistent calculations; (3) Two oxygen atoms at the 2b Wyckoff positions are removed from the model to balance the charge of the entire unit cell, and there is no Raman active modes at 2b Wyckoff positions.\footnote{[42]} Through these approximations, the unit cell of T-Nb$_2$O$_5$ shows higher space symmetry than the original Nb$_{16.8}$O$_{42}$ model and space group is Pbam.

### 3. Results and Discussion

The Nb$_2$O$_5$@RuO$_2$ heterostructures were obtained as schematically illustrated in Figure 1a. Firstly, layered potassium trinitiate (KNb$_3$O$_8$) and sodium ruthenate (NaRuO$_2$) were fabricated via solid-state reaction. Subsequently, layered protonic
trinitiobate (HNb₃O₈) and ruthenate (HRuO₂) were obtained by proton-exchange reaction with acid solution. The exfoliation of layered HNb₃O₈ and HRuO₂ were achieved by the intercalation of tetrabutylammonium (TBA) cation and followed by ultrasonic treatment, the exfoliated nanosheets (NSs) labeled as TBA-Nb₃O₈ NSs and TBA-RuO₂ NSs, respectively. Finally, TBA-Nb₃O₈ NSs and TBA-RuO₂ NSs were mixed and annealed treatment in air to convert precursors into Nb₂O₅@RuO₂ heterostructures. As shown in Figure 1b, the Nb₂O₅@RuO₂ heterostructures feature intimate interfacial interactions, which maximize the potential of conductive RuO₂ as support for Nb₂O₅. The ultrathin heterostructures significantly shortens the electrons/ions diffusion length, resulting in excellent rate capability.

**Figure 1.** Schematic illustrations of a) the synthesis process of Nb₂O₅@RuO₂. b) The lithium ions and electrons transportation process. SEM images of c) KNb₃O₈ and d) NaRuO₂. TEM images of e) TBA-Nb₃O₈ and f) TBA-RuO₂.
Scanning electron microscopy (SEM) and transmission electron microscopy (TEM) were employed to observe the morphology and microstructure of the precursors, intermediate products and final products. Both the SEM images of KNb$_3$O$_8$ and NaRuO$_2$ display obvious stacked layer structure (Figure 1c&1d). The particle size of NaRuO$_2$ (few dozen micrometers) is bigger than that of KNb$_3$O$_8$ (several micrometers). After chemical exfoliation by TBA, KNb$_3$O$_8$ and NaRuO$_2$ are transferred to TBA-Nb$_3$O$_8$ (Figure S1a) and TBA-RuO$_2$ (Figure S1b), respectively, realizing 2D nanostructures with well-defined morphology. The ultrathin morphologies of the TBA-Nb$_3$O$_8$ (Figure 1e) and TBA-RuO$_2$ (Figure 1f) are confirmed by TEM. The width of TBA-Nb$_3$O$_8$ NSs and TBA-RuO$_2$ NSs are approximately 200-500 nm and several micrometers, respectively. The X-ray diffraction (XRD) patterns of TBA-Nb$_3$O$_8$ and TBA-RuO$_2$ are displayed in Figure S2 and S3, exhibiting the characteristic peaks of the exfoliated nanosheets.$^{[35, 37]}$

**Figure 2.** a, b) SEM, c, d) TEM, e, f) HRTEM, g) HADDF-STEM images and corresponding h) Nb, i) Ru and j) O elemental mapping of Nb$_3$O$_8$@RuO$_2$. 
Figure 2a&2b clearly exhibit 2D nanosheets morphology of Nb₂O₅@RuO₂ with the size of about 2-10 μm. Figure 2c&2d further confirm ultrathin 2D nanosheets of Nb₂O₅@RuO₂ heterostructures, which maintains similar structure with precursors. The high-resolution transmission electron microscopy (HRTEM) images are revealed in Figure 2e&2f and Figure S4. Figure 2e shows the visible lattice fringes with a lattice spacing of 0.39 Å, which are consistent with the (001) plane of T-Nb₂O₅. Figure 2f and Figure S4 reveal the Nb₂O₅ and RuO₂ are twinborn on one nanosheet with a distinct interface, forming Nb₂O₅@RuO₂ heterostructures. The d-spacing value is measured to be 2.5 Å and 3.9 Å, corresponding to the (101) plane of RuO₂ and (001) plane of T-Nb₂O₅, respectively. The high angle annular dark-field scanning transmission electron microscopy (HADDF-STEM) and related energy dispersive X-ray spectrometry (EDS) elemental mapping (Figure 2g-2j) prove the Nb₂O₅ and RuO₂ NSs disperse uniformly in the Nb₂O₅@RuO₂ heterostructures.

The crystalline phase of Nb₂O₅, RuO₂ and Nb₂O₅@RuO₂ were studied by XRD (Figure S5a). The XRD patterns of Nb₂O₅ and RuO₂ exhibit the standard patterns of Nb₂O₅ (JCPDS No. 30-0873) and RuO₂ (JCPDS No. 40-1290), respectively. The XRD pattern of Nb₂O₅@RuO₂ heterostructures confirms that its composition contains both Nb₂O₅ and RuO₂. The construction of the Nb₂O₅@RuO₂ heterostructure reduces the particle size and crystallinity of RuO₂, which leads to weaker intensity and larger half width of the diffraction peak. Figure S5b displays the Raman spectra of Nb₂O₅, RuO₂ and Nb₂O₅@RuO₂. The RuO₂ shows three distinct peaks located at 523, 643 and 713 cm⁻¹. And the Nb₂O₅ exhibits four clearly peaks located at 126, 239, 687 and 990 cm⁻¹. In the case of the Nb₂O₅@RuO₂, distinct peaks with those of the RuO₂ and Nb₂O₅ confirm the formation of heterostructures. Figure S6 reveals the X-ray photoelectron spectroscopy (XPS) spectrum of Nb₂O₅@RuO₂, the typical shape peaks of Nb 4s, Nb 4p, Nb 3s, Nb 3p, Ru 3p, Ru 3d and O 1s species can be clearly observed in XPS survey spectrum, which demonstrates that the Nb₂O₅@RuO₂ includes Nb, Ru and O elements. The high-resolution XPS spectrum can analyze the chemical environment of every element in composites. According to the high-resolution Nb 3d XPS spectrum (Figure S7a), two remarkable peaks located at about 209.9 and 207.1 eV, analogous to Nb 3d₃/₂ and Nb 3d₅/₂, respectively. As for the high-resolution of Ru 3d (Figure S7b), the binding energies of about 284.8 and 280.6 eV match with Ru 3d₃/₂ and Ru 3d₅/₂, respectively. Compared with the pure Nb₂O₅ power, the peaks of Nb 3d exhibit slight shift to high bonding energy, demonstrating the enhanced valence state of Nb. Meanwhile, the peaks of Ru 3d display obvious shift to low binding energy.
bonding energy, revealing the decreased Ru valence state. The XPS results confirm that the Nb$_2$O$_5$ NSs possess strong interaction with RuO$_2$ nanosheets instead of simple physical blending, which is in good agreement with the results of HRTEM (Figure 2f). The chemical bonding of Nb$_2$O$_5$ NSs on RuO$_2$ NSs could maintain the stable structure after long cycles and the metallic RuO$_2$ NSs work as a cushion to buffer the volume change of Nb$_2$O$_5$ during lithiation/delithiation. The nitrogen absorption-desorption technique showed that Nb$_2$O$_5$@RuO$_2$ possessed the Brunauer-Emmett-Teller (BET) specific surface area of 30.8 m$^2$/g and pore size distribution of 0.7, 1.5, 4 nm, revealing the microporous and mesoporous structure of the hybrid material (Figure S8). The thermogravimetric analysis (TGA) was conducted to check the weight ratio of Nb$_2$O$_5$ in Nb$_2$O$_5$@RuO$_2$. The content of the RuO$_2$ and the Nb$_2$O$_5$ are about 17 wt.% and 83 wt.%, respectively (Figure S9a&b).

The electrochemical behavior of Nb$_2$O$_5$@RuO$_2$ as anode material for LIBs was evaluated in 2032 coin-type cell. Figure 3a displays the first four cyclic voltammetry (CV) curves of Nb$_2$O$_5$@RuO$_2$ at a scan rate of 0.1 mV s$^{-1}$ between a voltage window of 1.1-3.0 V (vs. Li$^+$/Li). During the first Li$^+$ insertion process, two reduction peaks located at 1.83 V and 1.5 V were observed, which is attributed to the redox reaction of Nb$_2$O$_5$ (Nb$_2$O$_5$ + x Li$^+$ + x e$^-$ = Li$_x$Nb$_2$O$_5$), accompanied by a little decomposition of electrolyte and formation of stable solid electrolyte interphase (SEI) layer.$^{[56-57]}$ The oxidation peaks were observed at around 1.75 V and 1.93 V during charge process, corresponding to the oxidation of Nb from Nb$^{4+}$ to Nb$^{5+}$. The CV curves almost overlap after the first cycle, revealing good reversibility after the initial capacity loss. The first three galvanostatic charge/discharge curves of Nb$_2$O$_5$@RuO$_2$ are shown in Figure 3b. The Nb$_2$O$_5$@RuO$_2$ delivers a reversible charge capacity about 285 mAh g$^{-1}$ at 1 C (1 C = 200 mA g$^{-1}$), with an initial Columbic efficiency (ICE) of 61.4%. The initial irreversibility may result from the SEI formation and irreversible Li$^+$ insert into Nb$_2$O$_5$ and RuO$_2$.$^{[17]}$ The typical charge/discharge profiles of RuO$_2$ were shown in Figure S10, the RuO$_2$ reacts with Li via conversation mechanism in the voltage window below 1.1 V. Thus, the capacity of Nb$_2$O$_5$@RuO$_2$ can be mainly attributed to the insertion reaction between lithium ion and Nb$_2$O$_5$. The cycling stability of the Nb$_2$O$_5$@RuO$_2$ and the Nb$_2$O$_5$ at 5 C are shown in Figure 3c. Obviously, the Nb$_2$O$_5$@RuO$_2$ shows higher reversible capacity (165 mAh g$^{-1}$ after 1000 cycles) than that of the Nb$_2$O$_5$ (129 mAh g$^{-1}$ after 1000 cycles). The capacity decay of the Nb$_2$O$_5$@RuO$_2$ (Figure 3c) was very slow, only 0.03% decay per cycle after the first three cycles at 1 C. The Nb$_2$O$_5$@RuO$_2$ not only displays excellent cyclability at a low
current density but also shows stable cycle life under a high current density. The SEM images of Nb$_2$O$_5$@RuO$_2$ for LIBs after 100 cycles at rate of 5 C is shown in Figure S11, it can still well maintain the 2D morphology. Figure 3d shows the cycling performance of the Nb$_2$O$_5$@RuO$_2$ electrode at 50 C. After the initial capacity loss, the Columbic efficiency reaches $\approx 100\%$. It delivers extraordinary long-life stability of around 97 mAh g$^{-1}$ at 50 C after 10000 cycles, which is higher than that of other Nb$_2$O$_5$-based anode for LIBs (Table S1).

Figure 3. a) CV curves for first four cycles at a scan rate of 0.1 mV s$^{-1}$. b) Galvanostatic charge/discharge curves for first three cycles at 1 C. c) Cycling stability at 5 C and d) Long-term cycling stability at 50 C of Nb$_2$O$_5$@RuO$_2$. e) Rate capacity at different rates.
as indicated of Nb$_2$O$_5$@RuO$_2$ and Nb$_2$O$_5$. f) A comparison of rate performance of Nb$_2$O$_5$@RuO$_2$ with some other reported Nb$_2$O$_5$ anode materials.

Figure 3e compares the rate performance of the Nb$_2$O$_5$@RuO$_2$ and the Nb$_2$O$_5$ NSs from 1 C to 100 C. The Nb$_2$O$_5$@RuO$_2$ electrode displays excellent rate capability and can be reversely cycled at 100 C. The Nb$_2$O$_5$@RuO$_2$ delivers reversible capacities of 280, 251, 222, 197, 170, 133 and 106 mAh g$^{-1}$ at 1, 2, 5, 10, 20, 50 and 100 C, respectively. In the case of Nb$_2$O$_5$ NSs electrode, at the same rate, it can only display low capacities of 186, 176, 160, 145, 124, 97 and 70 mAh g$^{-1}$, respectively. The enhanced lithium storage properties of the Nb$_2$O$_5$@RuO$_2$ heterostructures in comparison to Nb$_2$O$_5$ NSs may be attributed to its intimate interfacial interaction between T-Nb$_2$O$_5$ and the metallic RuO$_2$, leading to better ionic and electronic conduction throughout the electrode. To get the evidence of enhanced conductivity Nb$_2$O$_5$ NSs after introduction of the RuO$_2$, the electrochemical impedance spectroscopy (EIS) was carried out to test the both cells after 3 cycles at 1 C (Figure S12). The charge transfer resistance ($R_{ct}$) of Nb$_2$O$_5$@RuO$_2$ (60 Ω) shows more significant decrease than that of Nb$_2$O$_5$ (340 Ω), indicating the existence of RuO$_2$ may be beneficial to reduce polarization. The rate performance of Nb$_2$O$_5$@RuO$_2$ is superior to that of other Nb$_2$O$_5$-based anode for LIBs (Figure 3f), such as Nb$_2$O$_5$@Nb$_4$C$_3$T$_x$,[19] Ag-N-Nb$_2$O$_5$,[17] C-T-Nb$_2$O$_5$,[58] T-Nb$_2$O$_5$@C,[45] Wired-H-Nb$_2$O$_5$,[59] Nanoporous Nb$_2$O$_5$,[25] Nb$_2$O$_5$/HGF,[18] 3D/CNW-T-Nb$_2$O$_5$,[60] m-Nb$_2$O$_5$-C,[61] Nb$_2$O$_5$-600,[62] CN-NbO,[14] Nb$_2$O$_5$@C/CNTs,[30] and T-Nb$_2$O$_5$-NF.[15]
Figure 4. a) CV curves of Nb$_2$O$_5$@RuO$_2$ at various scan rates. b) Relationship between the peak currents and scan rates in logarithmic format. c) Capacitive contribution of Nb$_2$O$_5$@RuO$_2$ at a scan rate of 10 mV s$^{-1}$. d) Contribution ratio of the capacitive and diffusion-controlled capacity versus scan rate.

It has been demonstrated that a pseudocapacitive mechanism appears when lithium ions are inserted into T-Nb$_2$O$_5$.[63] To obtain the kinetics information of Nb$_2$O$_5$@RuO$_2$, CV tests were performed to study the electrochemical behavior of Nb$_2$O$_5$@RuO$_2$ at different sweep rates from 0.1 to 10 mV s$^{-1}$ (Figure 4a). We plotted the curves of log ($i$) versus log ($v$) for both oxidation and reduction peak current, where $i$ is current (mA) and $v$ is the sweep rate (mV s$^{-1}$). As displayed in the Figure 4b, the two parameters ($i$, $v$) obey a function relationship as follow$^{[13, 64]}$:

$$i = av^b$$  

(1)

$$\log(i) = \log(a) + b\log(v)$$  

(2)
Where $a$ and $b$ are two parameters of value from 0.5 to 1. It was agreed that $b = 0.5$ reveals a diffusion-controlled process resulted from Li$^+$ intercalation, and $b = 1$ implies a capacitive process by surface charge storage mechanism.\cite{65-66} In Figure 4b, the $b$ value calculated from cathodic and anodic peaks are 0.88 and 0.96, respectively, exhibiting the pseudocapacitive behavior of Nb$_2$O$_5$@RuO$_2$. It can explain why Nb$_2$O$_5$@RuO$_2$ achieved extraordinary rate performance. The current can be described as a sum of two parts at every potential value, which are capacitive contribution ($av$) and diffusion-limited contribution ($av^{1/2}$). Therefore, it can be written as follow:

\[ i = k_1v + k_2v^{1/2} \]  
\[ (3) \]

\[ i/v^{1/2} = k_1v^{1/2} + k_2 \]  
\[ (4) \]

Where $k_1$ and $k_2$ are two parameters, which can be easily work out according to Equation (4). According to the integral area of the CV curve, the contribution of capacitance is about 88% of the total charge storage (Figure 4c) at scan rate of 10 mV s$^{-1}$. The contribution ratios of capacitive and diffusion-controlled at different sweep rates have been calculated as shown in Figure 4d. The percentage of capacitive contribution continuously increases with the increases of sweep rate.

To further demonstrate the possibility of practical application, lithium-ion full cells were assembled by using commercial LiFePO$_4$ (LFP) as cathode and activated Nb$_2$O$_5$@RuO$_2$ as anode between 1.0 and 3.0 V, as the schematic illustration in Figure 5a.\cite{67-68} The XRD pattern and SEM image of LFP are shown in Figure S13 and Figure S14, respectively. The morphology of LFP is near-spherical with size of 1-10 μm. The typical charge/discharge curves of LFP half cell ranging from 2.2-4.0 V indicate a plateau around 3.4 V with a discharge capacity of 150 mAh g$^{-1}$ at 1 C (Figure S15). The LiFePO$_4$ electrode delivers the capacities of 158, 154, 150, 142, 125, 103, and 70 mAh g$^{-1}$ at 0.2, 0.5, 1, 2, 5, 10, and 20 C, respectively (Figure S16). Figure 5b shows the charge/discharge curves of LPF//Nb$_2$O$_5$@RuO$_2$ full cell at rate of 2 C to 50 C. The full battery delivers a reversible capacity of about 286 mAh g$^{-1}$ at 2 C with an average voltage plateau at 1.8 V (the specific capacity and current density are based on the weight of anode material). Figure 5c represents the rate capacity of full cell, delivering reversible capacities of 286, 230, 185, 140 and 90 mAh g$^{-1}$ at 2, 5, 10, 20 and 50 C,
respectively. Figure 5d shows the cycle performance of full cell at 20 C. Remarkably, the full battery maintains good cycling stability and exhibits high reversible capacity (82 mAh g\(^{-1}\) after 500 cycles) with Coulombic efficiency nearly reach 100%. The excellent electrochemical performance of the full cell confirms the potential of practical application of the Nb\(_2\)O\(_5\)@RuO\(_2\).

**Figure 5.** a) Schematic illustration of the Nb\(_2\)O\(_5\)/LiFePO\(_4\) full cell. b) The charge/discharge curves of full cells at various current densities. c) Rate performance and d) long cycle performance for 500 cycles at 20 C.

The Li ions migration barriers in Nb$_2$O$_5$ and Nb$_2$O$_5$@RuO$_2$ along d) path 1 and e) path 2.

The density functional theory (DFT) calculations were performed to explain the lithium storage mechanism and ions transport in Nb$_2$O$_5$ and Nb$_2$O$_5$@RuO$_2$. The structure of the Nb$_2$O$_5$ crystal is obtained after structural optimization. The atomic arrangement along the c-axis direction is formed by the stacking of 4h layers and 4g layers in turn, of which 4h layers become the primary Nb-O bonding layers, while the 4g layers are completely occupied by oxygen atoms (Figure 6a). The larger spatial gap makes the 4g layer an ideal layer for lithium ions adsorption and bonding. Similarly, the structure-optimized Nb$_2$O$_5$/RuO$_2$ heterojunction system is prepared for subsequent...
Theoretical calculations (Figure 6b). We found eight possible lithium ions adsorption sites on the Nb$_2$O$_5$ through structure optimization (Figure 6a), and the corresponding adsorption energy values of different adsorption sites (labeled in Figure 6a) range from -3.31 eV to -3.53 eV (Figure 6c and Table S2). Besides, the lithium ions adsorption energy on Nb$_2$O$_5$@RuO$_2$ (labeled in Figure 6b) range from -3.98 to -4.17 eV (Figure 6c and Table S2). The adsorption energy of lithium ions among Nb$_2$O$_5$ and Nb$_2$O$_5$@RuO$_2$ are shown in Figure 6c, revealing the introduction of the RuO$_2$ layer improves the stability of lithium ions adsorption on the T-Nb$_2$O$_5$ 4g layer. Then, we simulated the diffusion barrier of lithium ions in the 4g layer along the x-y plane of Nb$_2$O$_5$ and Nb$_2$O$_5$@RuO$_2$ using the Climbing Image Nudged Elastic Band (CINEB) method. We simulate the two possible diffusion systems, namely: path 1 is that lithium ions transport from site 4 to another site 4 of the nearest neighbor lattice and path 2 is lithium ions transport path from site 4 to nearest stable site 5 in the same unit cell. The lithium ions diffusivity related migration barriers of Nb$_2$O$_5$ along path 1 and path 2 are summarized and compared with those of Nb$_2$O$_5$@RuO$_2$ in Figure 6d and Figure 6e, respectively. The results show that the diffusion of lithium ions in the Nb$_2$O$_5$@RuO$_2$ requires lower energy barriers than those of Nb$_2$O$_5$. In summary, our first-principles calculations show that the presence of the RuO$_2$ layer indeed improves the stability of lithium ions adsorption and reduces the diffusion barrier of lithium ions in the Nb$_2$O$_5$, which is consistent with the previous experimental results.

4. Conclusions

In summary, Nb$_2$O$_5$@RuO$_2$ heterostructures have been synthesized via a top-down liquid exfoliation strategy and followed by annealing in air. The intimate interfacial interaction between T-Nb$_2$O$_5$ and the metallic RuO$_2$ combine the collective merits of Nb$_2$O$_5$ NSs and RuO$_2$ NSs and facilitate the synergistic advantages. The metallic RuO$_2$ can enhance the electronic conductivity of Nb$_2$O$_5$ and realize fast Li accessibility. The 2D structure of Nb$_2$O$_5$ with high surface can shorten the diffusion path of ions and electrons. The Nb$_2$O$_5$@RuO$_2$ endows remarkable rate performance (133 mAh g$^{-1}$ and 106 mAh g$^{-1}$ at 50 C and 100 C, respectively) and excellent long-life capacity (100 mAh g$^{-1}$ after 10000 cycles at 50 C). The kinetic analysis reveals the pseudocapacitive storage process of Nb$_2$O$_5$@RuO$_2$, which enhances the electrochemistry performance at rapid charge and discharge process. Furthermore, Nb$_2$O$_5$@RuO$_2$/LiFePO$_4$ full cell also delivers capacities of 140 mAh g$^{-1}$ and 90 mAh g$^{-1}$ at 20 C and 50 C, respectively, indicating its excellent electrochemical performance. The computation results...
demonstrate that the strong Li adsorption on the 2D Nb₂O₅@RuO₂ heterostructures leads to its remarkable electrochemical performance. This work paves the way to construct a variety of heterostructures for other applications (i.e. energy storage, catalysis, and sensor).

All the formatting changes are as follows:

1. Graphical Abstract

The Graphical Abstract is required by all articles. Please provide us a Graphical Abstract, including one summary figure of your article in TIFF or JPEG format and a short summary of your work (less than 150 characters rather than 150 words). Please note that all figures should be free of copyright restrictions, or you can supply a new image describing your work.

**Response:** We have provided a Graphical Abstract, including one summary figure of our article in TIFF format and a short summary of our work.

![Graphical Abstract](image)

The 2D Nb$_2$O$_5$@RuO$_2$ heterostructures possess short diffusion length of ions/electrons, easy penetration of liquid electrolyte, and high conductivity transport of electrons.

2. Figures

Please adjust all the figures to their proper positions in the main text.

**Response:** We have adjusted all the figures to their proper positions in the main text.

3. Author's Contribution

Please add the Author's Contribution according to References of the attached Manuscript Submission Template. The description can be up to several sentences long and should briefly describe the tasks of individual authors. e.g., A, B conducted the
research; C, D analyzed the data; A, B wrote the paper; ...; all authors had approved the final version. Acquisition of funding, collection of data, or general supervision of the research group, alone, does not justify authorship.

**Response:** We have added the Author's Contribution.

4. Conflict of interest

Authors should declare whether or not the submitted work was carried out with a conflict of interest. If yes, please state any personal, professional or financial relationships that could potentially be construed as a conflict of interest. If no, please add "The authors declare no conflict of interest".

**Response:** We have added "The authors declare no conflict of interest".

5. References

Please revise the mode of citation according to References of the attached Manuscript Submission Template.

- Please make sure the format of the authors’ name in references is "the first name, the last name".
- Please delete the ending page number and the volume number.
- Please check that the references are up to date.
- Please remove any references that are unpublished and move them to the text, if applicable.

**Response:** We have revised the mode of citation according to References of the attached Manuscript Submission Template.

6. Please provide the ORCID ID of corresponding author.
Response: We have provided the ORCID ID of the corresponding author.
